Both design cases have been formulated in non-linear programming form and are numerically solved with the method of feasible directions. The feasible directions algorithm is a primal optimization method, and performs a direct search of the feasible design space based on first order sensitivity for objective function and constraints. Primal methods are more suitable for designs involving computationally expensive constraints, like the present one, since they typically require fewer constraint evaluations than the penalty transformation methods. The feasible directions method used in this study incorporated active constraint set, and line-search strategies for improved efficiency. CASE STUDIES Assumptions Applications Studies were performed regarding the optimal tailoring of a plate composite link in long, in wide, and in thick. This simple composite link was selected in 10.26 of order to obtain an initial assessment. It merits the present design methodology and of to identify the important design parameters. finite element mesh nodes and of 5580 A plate triangular elements was used as...
